

UNITED STATES PATENT APPLICATION

By: Jamieson William Maclean Crawford and Stefanie Livanos

FOR: BLOOD COLLECTION SET

BACKGROUND OF THE INVENTION

1. Field of the Invention

[0001] The subject invention relates to a blood collection set having a needle cannula and a shield that can be driven forwardly to safely shield the needle cannula.

2. Description of the Related Art

[0002] A prior art blood collection set includes a small diameter needle cannula having a pointed distal end and a proximal end mounted to a thermoplastic hub. Portions of the blood collection set near the hub may be provided with a pair of flexible wings. The wings can be folded into face-to-face engagement with one another to facilitate digital manipulation of the small needle cannula. The wings then can be folded away from one another and taped into face-to-face engagement with the skin of the patient near a puncture site. The prior art blood collection set further includes a flexible plastic tube that has one end connected to the hub and an opposed end connected to a fitting. The fitting can be placed in communication with a reservoir to which collected blood may be directed.

[0003] The needle cannula of the prior art blood collection set typically is shielded prior to and after use to prevent accidental sticks. Needle shields used with prior art blood collection sets have taken many forms. Typically, a prior art blood collection set is packaged with a rigid tubular cap telescoped over the needle cannula to prevent accidental sticks prior to use. This tubular cap is removed from the needle cannula immediately prior to use of the blood collection set. Most prior art blood collection sets further include a second shield that is telescoped over the needle cannula and hub. The second shield may include at least one slot through which

wings of the prior art hub may extend. Thus, the medical technician who uses the prior art blood collection set will hold the wings of the needle hub in one hand and the shield in the other hand after removing the needle cannula from the patient or blood donor. The wings then are slid proximally relative to the shield, thereby drawing the needle cannula into the shield. Some prior art shields are configured to engage the wings when the needle cannula has been shielded to make a re-exposure of the needle cannula difficult.

[0004] The digital manipulation that is required to shield the used needle cannula of a prior art blood collection set creates the potential for generating the accidental needle stick that the shield is intended to avoid. In particular, it is undesirable to rely upon a shielding that requires two hands to be moved in opposite directions in proximity to the point of a used needle cannula. Accordingly, the inventors herein have recognized the desirability of providing an automatically shieldable needle cannula for a blood collection set.

#### SUMMARY OF THE INVENTION

[0005] The subject invention relates to a blood collection set which comprises a needle cannula having a proximal end, a pointed distal end and a lumen extending therebetween.

[0006] The blood collection set further includes a hub that may be molded from a thermoplastic material. The hub includes proximal and distal ends. The hub also has inner and outer tubes that extend between the proximal and distal ends. The inner tube includes a passage that extends continuously between the proximal and distal ends of the hub. A portion of the inner tube at the distal end of the hub is securely mounted to the proximal end of the needle cannula. Thus, the lumen through the needle cannula communicates with the passage through the hub. The inner and outer tubes are connected to one another adjacent the proximal end of the hub. However, a cylindrical space exists at other locations between the inner and outer tubes and is open from the distal end of the hub. The outer tube includes an aperture extending therethrough and into the cylindrical space between the inner and outer tubes at a location near the proximal end of the hub.

**[0010]** The blood collection set further comprises a retainer for releasably retaining the shield in the proximal position relative to the hub and the needle cannula and against the stored energy of the biasing means. The retainer may define a resiliently deflectable actuating finger that projects into the aperture in the outer tube of the hub. The end of the actuating finger may be depressed to separate the actuating finger from the aperture and enable the shield to be propelled toward the distal position in response to forces exerted by the biasing means.

## DESCRIPTION OF THE DRAWINGS

[0011] FIG. 1 is a perspective view of a blood collection set in accordance with the subject invention with the needle exposed.

[0012] FIG. 2 is a cross-sectional view taken along line 2-2 in FIG. 1.

[0013] FIG. 3 is a perspective view similar to FIG. 1, but showing the needle of the blood collection set in the shielded condition.

## DETAILED DESCRIPTION

[0014] A blood collection set in accordance with the subject invention is identified generally by the numeral 10 in FIGS. 1-3. Blood collection set 10 includes a needle assembly 12 which comprises a needle hub 14, a needle cannula 16, a safety cap (not shown), a shield 20 and a spring 22. Hub 14 includes a proximal end 32 and a distal end 34. A tubular inner wall 36 extends from proximal end 32 to distal end 34 and is connected to needle cannula 16 as in the prior embodiments. A tubular outer wall 38 is disposed in concentric spaced relationship around tubular inner wall 36. Tubular outer wall 38 is formed with a retention aperture 40 extending therethrough at a location near proximal end 32. Wings 66 extend transversely from tubular outer wall as in the prior embodiments.

[0015] Shield 20 is telescoped between inner and outer walls 36 and 38 of hub 14 and includes a proximal end 42 and a distal end 44. A resiliently deflectable finger 46 projects proximally and outwardly from a location between proximal and distal ends 42 and 44. Finger 46 includes an actuator 48 that is releasably engaged in retention aperture 40 of outer wall 38 on hub 14. Spring 22 is captured in a compressed condition between proximal end 32 of hub 14 and shield 20.

[0016] Needle assembly 12 is used in the conventional manner. After withdrawal of needle cannula 16 from the patient, shield 20 is activated merely by exerting a pressing force on

actuator 48. This pressing force will disengage actuator 48 from aperture 40 and shield 20 will be propelled distally into surrounding shielding disposition relative to needle cannula 16. After sufficient distal movement, resiliently deflectable finger 46 will pass beyond distal end 34 of hub 14 and will resiliently move into a position aligned with portions of outer wall 38 at distal end 34. Thus, re-exposure of needle cannula is substantially prevented. On the other hand, engagement between an inwardly directed flange at distal end 34 of hub 14 and an outwardly directed flange on shield 20 prevents complete separation of shield 20 from hub 14.
